Abstract

In this study, the development of auto tuning control in a perfusion system for Extracorporeal Membrane Oxygenation (ECMO) support is described. ECMO is a temporary life support system used for patients whose heart or lungs are not working properly. This system must be managed by a perfusionist to maintain proper blood flow and blood pressure to the patient. In this paper, the control of blood-gas process of an ECMO system is modeled in a detailed approach in MATLAB Scripts. Experimental results show a good agreement in static and frequency domain measurements.
