ABSTRACT
Mobile Ad-hoc network is a situate of portable nodes that correspond with wireless links and communication acknowledged out without any central control or fixed communication. The dynamic topology of MANETs allows nodes to join and leave the network at any point of time. This generic characteristic of MANET has rendered it vulnerable to security attacks. The black hole attack is one of such security risks. In this attack, a malicious node fallaciously advertises shortest path to the destination node with an intention to disrupt the communication. In this paper, we intend to solve the problem to break the link hole attack in one of the most prominent routing algorithms, ad-hoc on demand distance vector (AODV) routing, for the MANETs. The anticipated scheme uses Watchdog mechanism to detect malicious node with usage of local information of intermediate node and propagates the information of black hole node to all other node in network. The simulation results show the efficiency of anticipated scheme in presence of black hole node.

Keywords
ad hoc networks, black hole, AODV, security, routing.

1. INTRODUCTION
A mobile ad hoc network is a set of wireless mobile nodes that dynamically establishes the network in the absence of fixed communication. One of the individual features of MANET is, each node must be able to find the optimal path to forward a packet. MANET provides the technology for civilian and military applications. One of the important research areas in MANET is starting and maintaining ad hoc network through the use of routing protocols. The increasing development in wireless local area networks has opened new limits in the field of telecommunication. MANET is composed of nodes that can communicate with each other without knowing their position. There is no base station in these networks. Nodes communicate in multi-hop pattern. These networks are needed in conditions where short-lived connectivity is required.

There are two well known secured-initiated on demand routing protocols include AODV and DSR. These protocols are based on plan of finding valid paths once they are needed by the source node. This procedure, known as route discovery engage the route request phase (RREQ) and route reply phase (RREP). All of these protocols construct a single-path route between a source node and a destination node. Whenever communication link breaks on the active route, each protocol has to raise a route discovery process to cause the performance badly. Single path protocols learn Routes and select a single best route to reach each destination.

2. OVERVIEW OF AD HOC ON-DEMAND DISTANCE VECTOR ROUTING PROTOCOL
AODV stands for ad hoc on-demand distance vector routing protocol. AODV is a reactive protocol. AODV is a single path distance vector routing protocol in ad hoc wireless networks. This protocol mixes the route discovery mechanism in DSR with the approach of destination sequence number in DSDV. Basically when there is one node that wants to communicate with another node that is not in range, it finds a route through the other nodes. It minimizes the number of broadcasts by creating routes on-demand as opposed to all possible routes as in DSDV. AODV is a loop-free, single path, distance vector protocol based on hop-by-hop routing approach. There are two main procedures in AODV:

1. Route discovery
2. Route maintenance

1. Route Discovery
When source node wants to communicate with destination and if path is not available to destination then source node rebroadcast to its entire neighbor in the network. When intermediate node receives RREQ, they create link to previous node. They first of all check whether valid route to destination or present. If valid route is present then another condition is hold, i.e. intermediate node’s sequence number should be at least as great as destination sequence number in RREQ packet. If both condition hold then that node generate RREP packet. If valid route is not present then RREQ is further forwarded. RREP contains IP address of source node as well as destination and destination sequence number once the node creates the forwarded route entry. If forwarded the RREP to destination node. The RREP is thus forwarded hop-by-hop to the source node. Once receives the RREP. It can utilize the path for the transmission of data packet.

2. Route Maintenance
As MANET is dynamic i.e. mobility and topology of nodes always change, link break occurs, when path breaks both nodes informs their end nodes about link failure who were using path by sending RERR. End nodes delete their entry from route table as path is no longer useful. If source nodes still want to communicate with destination. If reinitiate RREQ broadcasting or path finding process or repair broken link.

opinion of the neighbors of the node (say, node A) which replied with a RREP packet, i.e., advertises the shortest route to the destination. This opinion along with a rule base determines whether node A is malicious. Mahmood and Khan [10] present a survey of methods to combat black hole attack on AODV routing protocol.

4. PROPOSED SCHEME FOR BLACK HOLE DETECTION AND PREVENTION

In proposed system we have merged two techniques for detection and prevention of black hole. In which, each and every node observes the other node into the network using watchdog mechanism. First source node broadcast RREQ for finding the best route towards the destination. Intermediate node process the RREQ based on, its originator or it does not know the destination location so that it further broadcast RREQ. At that time source node observes the intermediate node and increment the credit value. Credit value increases based on RREQ broadcast or forward data packet. Credit value decreases based on receive route reply RREP or drop the data packet. Attacker node never broadcast RREQ message so we consider this issue for our proposed work. When credit value reached at the zero intermediate node itself modify RREQ message and add the malicious node ID in modify RREQ, so that each and every node remove the entry of malicious node for prevention technique. Based on this scheme it prevents black hole attacker and increase the parameter like throughput, routing overhead and PDR

5. SIMULATION AND RESULT

we have setup experiment in which we have taken two network simulation scenarios in which first we have checked the behavior of normal AODV protocol under various performance parameters and second we have checked the behavior of AODV protocol under some malicious behavior

Simulation parameters are given in following Table 1.

<table>
<thead>

6. CONCLUSION
MANET is an emerging area as it has great potential in various diverse areas, e.g., military, disaster management, intelligent transportation system, monitoring, public safety. However, it poses a greater security risk in comparison to conventional wireless and wireless networks due to its inherent characteristics, e.g., the open medium, dynamic network topology, autonomous terminal, lack of centralized monitoring, lack of management point Mobile. In this paper, we discuss black hole problem which is severe security risk in routing. We propose a method which is combination of watchdog mechanism and credit based technique in which we can take advantage of both for in which watchdog mechanism uses local information of routing table so it decreases the extra overhead so using these two technique we have tried to improve the results which we can see in graph. The simulation results show effectiveness of proposed method.
