ABSTRACT
With the rapid development in the technology, Encryption is one the most power full approach to achieve data security and privacy. Data Encryption techniques is used to hide the original content of a data in such a way that the original information is recovered only through using a key known as decryption process. The objective of the encryption is to secure or protect data from unauthorized access in term of viewing or modifying the data. Encryption can be implemented occurs by using some substitute technique, shifting technique, or mathematical operations. By applying these techniques we can generate a different form of that data which can be difficult to understand by any one. The original data is referred to as the plaintext and the encrypted data as the cipher text. Several symmetric key base algorithms have been developed in the past year. In this paper we proposed a comparative study over symmetric key based algorithm using some parameter like algorithm strength, key size, key type attack type etc.

Keywords
Symmetric, Encryption, Decryption, Substitution, Transposition, Plaintext, Cipher text.

1. INTRODUCTION
Cryptography is the art of achieve security by encoding messages to make them non-readable [1]. It is a technique which allow human-being to encrypt the data in such a way that the decryption can be performed without the aid of sender. Cryptography not only protects the information but also provides authentication to the user. As the network technology has been greatly advanced, there is a need to send much information via the Internet. Data can be read and understood without any special measures are called plaintext. Cryptography plays an important role in securely communication over the network and it provides an best solution to offer the necessary protection against the data intruders. Cryptography is the science of securing data. Cryptography is way of implanting mathematics to encrypt and decrypt data. Cryptography provides you to store sensitive information or transmit it across the insecure networks so that cannot be read by anyone except the intend recipient. Classical cryptanalysis involves an interesting combination of analytical reasoning, application of mathematical tools, pattern finding, patience, determination, and luck. Cryptanalysts are also called attackers. Cryptology embraces both cryptography and cryptanalysis [3, 4]. During communication, the sender performs the encryption with the help of a shared secret key and the receiver performs the decryption. Cryptographic algorithms are broadly classified as Symmetric key cryptography and Asymmetric key cryptography. This section elucidate about services and mechanisms of cryptography, processing approaches of plaintext, key distribution and cryptanalysis.

2. VARIOUS DIMENSIONS OF CRYPTOGRAPHIC SYSTEMS
There are various independent dimensions of cryptographic system.

2.1 Type of Encryption Technique Include
I. Substitution  
II. Transposition

2.2 Number of Keys Includes
I. Single-key or private  
II. Two-key or public

2.3 Number of Way in Which Plaintext is processed
I. Block  
II. Stream

3. SERVICE OF CRYPTOGRAPHY SYSTEM
Cryptography provides a number of security services to ensure the privacy of data. That why due to security benefit of cryptography, is widely used now a days. There are following service of Cryptography discussed below:

3.1 Confidentiality
Transmitted Information has to be accessed only by the authorized party.

3.2 Authentication
The information received by any system has to check the identity of the sender that whether the information is arriving from an authorized person.

3.3 Integrity
Only the authorized party is allowed to modify the transmitted information.

3.4 Access control
The Prevention of unauthorized use of a resource i.e. this service controls who can have access to a resource, under what condition access can occur, and what those accessing the resource are allowed to do.

3.5 Non-Repudiation
Provides protection against denial by one of the entities involved in a communication of having participated in all or part of communication.

4. SYMMETRIC CIPHER MODEL
A symmetric encryption model has following component fig. 4.1

4.1 Plaintext
This is the original intelligible message or data that is fed into algorithm as input.

4.2 Cipher text
The encoded message send to other side over network.

4.3 Key
Information used in cipher known only to sender/receiver.

4.4 Encryption Algorithm
Performs various substitution and transformation on the plaintext to convert cipher text

4.5 Decryption Algorithm
Encryption algorithm run in reverse to recovering original message from cipher text.

There are two building blocks of all encryption techniques are-

a). Substitution Technique: A substitution technique is one in which the letters of plaintext are replaced by other letters or by number or symbols. If the plaintext is viewed as a sequence of bits, then substitution involves replacing plaintext bit patterns with cipher text bit patterns. There are following substitution technique – Caesar Cipher, Monoalphabetic Cipher, Playfair Cipher, Hill Cipher, Polyalphabetic Cipher etc.

b). Transposition Techniques: A very different kind of mapping is achieved by performing some sort of permutation on the plaintext letters in which plaintext characters are shifted in some regular pattern to from cipher. This technique is referred to as a transposition cipher. The simplest such
cipher is the Rail Fence technique, Column Transposition, Odd-Even, Plaintext.

6. DIFFERENT SYMMETRIC KEY ENCRYPTION TECHNIQUE AND COMPARISON TABLE

This paper describes about some of the substitution and transposition encryption techniques which are already available. In general cryptographic encryption techniques are classified as classical encryption techniques and modern cryptographic techniques based on the periods that are developed/used. Classical cryptographic techniques are developed in the earliest days, but still some of the algorithms are used for providing confidentiality to the information. Modern cryptographic techniques are developed in recent years for providing better services like confidentiality, authentication, etc., to the information. In order to increase the degree of security, the modern cryptographic techniques algorithms are incredibly complex than classical cryptographic algorithms. Some of modern cryptographic algorithms are designed in such a way that repeats same procedure for many rounds, for example Feistel network, etc. Besides, symmetric encryption techniques also have encryption algorithms in both of classical and modern cryptographic techniques. For example play fair cipher, one time pad, hill cipher, etc. are comes under classical cryptographic techniques, and DES, AES, etc are modern cryptographic techniques. Here existing symmetric encryption algorithms are compared based on the parameters like block size, size of key, vulnerability to attacks and uniqueness of the technique, which are depicted as tabulation. Table I portrays the comparison of classical encryption techniques that are already exist.

7. CONCLUSION

In this paper, the limitations and weaknesses of classical encryption algorithms like Caesar cipher and Transposition cipher are described. It is used to achieve the mains of security aim like confidentiality, integrity, authentication, non-repudiation. In order to achieve these goals, Several algorithms have been developed in the past year and by comparison of different parameters used in algorithms give
significance of the algorithms In which some of the algorithms are succeed and others failed due to lack of security. The algorithm for encryption can be selected based on the type of data being communicated and type of channel through which data is being communicated. The main aim of this paper is to provides the fundamental knowledge about the cryptographic algorithms and comparison of available symmetric key encryption techniques based on some parameters like brute force attack, Key factor of Uniqueness about the technique, etc.
