ABSTRACT
Orthogonal Frequency Division Multiplexing (OFDM) is the most desired and attractive among the various broadband wireless communication system because of its robustness against multipath fading. However even after its so many advantages OFDM has been able to deliver up to its potential due to its “High Peak to Average Power Ratio (PAPR)” which causes power inefficiency in RF section of the transmitter effecting the throughput. The soul purpose of this paper is to provide the most effective PAPR reduction technique while doing amendments in the Partial Transmit Sequence and is termed as the modified Partial Transmit Sequence which overcomes the limitation of conventional system in which a property of cyclically shifting of IFFT is used which doesn’t require the side information and provides a system with low complexity.

Keywords
PAPR, PTS, IFFT, CCRR.

1. INTRODUCTION
Orthogonal frequency division Multiplexing (OFDM) is a Multicarrier modulation technique where multiplle data streams are modulated with mutually orthogonal carrier. In OFDM a high rate data stream is divided into a various number of lower rate data streams which would eventually get transmitted over a number of subcarriers simultaneously [1]. These subcarriers are overlapped with each other in order to increase the spectral efficiency hence providing desired resource utilization. One of the major attractive and effective feature of OFDM is its efficiency in utilization of the available network spectrum also stating its capability to effectively utilize the various other desired resources. Among the different effective and advantageous attributes some of the most popular are as its immunity to the inter-symbol interference, its robustness with respect to multipath fading and ability for effectively transfer high data rates. Due to its high spectrum efficiency and channel robustness it is used in digital audio/videos for high speed communication .The major drawback of OFDM is high PAPR which causes nonlinear distortion. Many techniques has been designed to overcome this PAPR issue in which conventional PTS is an attractive and most adopted method [2].

In this paper we proposed modified partial transmit sequence to reduce the peak-to-peak-average ratio (PAPR) in orthogonal division multiplexing (OFDM) system. The proposed technique uses the cyclically shifting property of IFFT which doesn’t require the explicit transmission of side information which is required in conventional partial transmit sequences (PTS) technique [3].

2. PAPR IN OFDM SYSTEM
Consider the N input blocks of length N which is given as $(x_n, n = 0,1, ..., N-1)$. Each symbol modulates a single set of subcarriers $(f_n, n = 0,1,2, ..., N-1)$. The chosen subcarriers are orthogonal and given as $f_n = n\Delta f$ in frequency domain where $\Delta f = \frac{1}{NT}$. $T$ is the duration of symbol. Thus, the transmitted OFDM signals is given as:

$$\chi(t) = \frac{1}{\sqrt{N}} \sum_{k=0}^{N-1} x_k e^{j2\pi kf}, \quad 0 \leq t \leq NT$$

Where \(j=\sqrt{-1}\), Figure 1 shows the block diagram of OFDM system.

PAPR in OFDM signal is defined as the ratio of maximum instantaneous power and its average power which is given as:

$$PAPR = \frac{\max|x(t)|^2}{E|x(t)|^2}$$

Where $E$ denotes the expectation operator. PAPR and in dB it is calculated and given as $PAPR = 10 \log_{10}(PAPR)$. 

3. PROPOSED METHOD
The proposed method is an effective solution to the problem of high PAPR in OFDM system. The proposed method is termed as modified Partial Transmit Sequence (PTS) which overcomes the limitation of conventional PTS technique as it doesn’t require the explicit transmission of side information which is required in conventional PTS technique. The proposed technique uses the cyclically shifting property of IFFT which doesn’t require the explicit transmission of side information and provides a system with low complexity.

4. SIMULATION RESULTS
The proposed method is simulated in MATLAB and the results are shown in Section IV. The results show that the proposed method provides a significant reduction in PAPR compared to conventional PTS technique. The proposed method also provides a system with low computational complexity.

5. CONCLUSION
The proposed method provides an effective solution to the problem of high PAPR in OFDM system. The proposed method is termed as modified Partial Transmit Sequence (PTS) which overcomes the limitation of conventional PTS technique as it doesn’t require the explicit transmission of side information which is required in conventional PTS technique. The proposed technique uses the cyclically shifting property of IFFT which doesn’t require the explicit transmission of side information and provides a system with low complexity.
3. PROPOSED METHOD

3.1 Conventional Partial Transmit Sequence (C-PTS)

Conventional Partial Transmit Sequence C-PTS is the most halsen technique for the reduction of PAPR in OFDM system. The PTS model is shown in figure 2. $X$ denotes the data block and given as a vector:

$$X = [X_0, X_1, ..., X_N]$$

The above vector $X$ is divided into $M$ disjoint subblocks and represented by vector:

$$X = \sum_{m=1}^{M} X_m$$

All the subcarrier that are presented in another subblock. An IFFT is employed as:

$$x = \text{IFFT} \{X\}$$

Applying phase rotation sector to each subblock:

$$b_m \in \{\pm 1, \pm j\}$$

Where $b_m, m = 1,2,3, ..., M$, we can set weighting factor $b_1 = 1$, where the optimum phase sequence is analyzed which minimizes PAPR of the OFDM signal[4,5].

$$x' = [x_1, x_2, ..., x_m]$$

$$x' = \sum_{m=1}^{M} b_m x_m$$

And $\{b_1, b_2, ..., b_m\} = \text{arg \, min} \, [\sum_{m=1}^{M} b_m |x_m|^2]$

For directly computing the signal the equation we can use the equation (8) when they have only different in sub-block $m$.

$$X = \sum_{m=1}^{M} \overline{x}(k)$$

Where the shifting number is $k$, for sub-block signals $x^m$ and $\overline{x}(k)$ is:

$$\overline{x}(k) = \text{circular}(x^m, k)$$

$$= [x^m(k), ..., x^m(LN-1), x^m(0), ..., x^m(k-1)]$$

Thus the subblocks can be generated by using the equation 10 and the sequence should be chosen with the minimum value of PAPR for transmission [8]. Figure 3 depicts the OFDM structure with the modified PTS scheme.

$$x_2 = x_1 - \left(x^m - \overline{x}(k)\right)$$

![Figure 2. Block diagram of Conventional PTS](image1)

![Figure 3. Block diagram of M-PTS Scheme](image2)

3.2 Modified PTS Scheme (M-PTS)

This scheme is the amended version of conventional PTS scheme as it lowers the complexity of the transmitter and the receiver without the help of side information. Unlike the C-PTS, this modified version generates a sequence by cyclically shifting the signals and then combining them together and given as [6,7]:

$$X = \sum_{m=1}^{M} \overline{x}(k)$$

Where the shifting number is $k$, for sub-block signals $x^m$ and $\overline{x}(k)$ is:

$$\overline{x}(k) = \text{circular}(x^m, k)$$

$$= [x^m(k), ..., x^m(LN-1), x^m(0), ..., x^m(k-1)]$$

For directly computing the signal the equation we can use the equation (8) when they have only different in sub-block $m$.

$$x_2 = x_1 - \left(x^m - \overline{x}(k)\right)$$

Thus the subblocks can be generated by using the equation 10 and the sequence should be chosen with the minimum value of PAPR for transmission [8]. Figure 3 depicts the OFDM structure with the modified PTS scheme.
3.3 Analysis of Computational Complexity for the C-PTS and the M-PTS

The computational complexity for the C-PTS and the modified PTS has been analyzed for transmitter and the receiver.

3.3.1 Computational Complexity for the Transmitter

In this section the computational complexity of the proposed scheme is compared with the C-PTS and other low complexity PTS schemes.

When the number of subcarriers is \( N = 2^n \) and the oversampling factor is \( L = 2^l \). The numbers of complex multiplications and complex additions required for the conventional PTS scheme can be express as follows:

The \( LN \)-point IFFT requires \( LN / 2 \log_2 (LN) \) numbers of complex multiplication \( (n_{mul}) \) and \( LN \log_2 (LN) \) numbers of complex addition \( (n_{add}) \) thus for the C-PTS the total \( n_{mul} \) and \( n_{add} \) are given as \( LN/2 \log_2 (LN/M) \) and \( LN \log_2 (LN/M) + W^{(M-1)}(M-1)LN \) respectively.

While for the modified PTS scheme, the total \( n_{mul} \) and \( n_{add} \) are given as \( LN/2 \log_2 (LN/M) \) and \( LN \log_2 (LN/M) + W^{(M-1)}2LN \), respectively.

3.3.2 Computational Complexity for the Receiver

The computational complexity for both receivers of modified PTS and C-PTS are divided in two parts-

(i) A \( LN \)-point FFT operation and

(ii) The detector

The overall computational complexity for the C-PTS scheme is:

\[
\begin{align*}
 n_{mul} &= LN/2 \log_2 \left( \frac{L^2 N^2}{M} \right) + (Q + 2) N \\
 n_{add} &= LN \log_2 \left( \frac{L^2 N^2}{M} \right) + W^{(M-1)}(M-1)LN + 2QN
\end{align*}
\]

While the overall computational complexity for the modified PTS scheme is:

\[
\begin{align*}
 n_{mul} &= LN/2 \log_2 \left( \frac{L^2 N^2}{M} \right) + (Q + 2)WN \\
 n_{add} &= LN \log_2 \left( \frac{L^2 N^2}{M} \right) + W^{(M-1)}2LN + 2QWN
\end{align*}
\]

The computational complexity reduction ratio (CCRR) of the modified PTS scheme over the C-PTS scheme is defined as \([8,9,10]\):

\[
CCRR = \left( 1 - \frac{\text{Complexity of the modified PTS}}{\text{Complexity of the C-PTS}} \right) \times 100\%
\]

In table 1 the comparison for the different values of CCRRs is shown in between C-PTS and the M-PTS for different values of M & N.

4. SIMULATION RESULTS

The analysis has been done with the help of MATLAB and several simulations results are assess which describes that modified PTS shows better performance in comparison to C-PTS. In this QPSK modulation scheme is used. The evaluation of the performance is analysed in terms of complementary cumulative distribution function.

Figure 4. PAPR performance of C-PTS and normal OFDM

In Figure 5 comparison between the proposed modified PTS scheme (C-PTS) with conventional PTS scheme is shown and we found that CCDF of proposed C-PTS scheme is superior.
5. CONCLUSION

In this paper, a modulated PTS scheme with reduced complexity has been proposed. In this approach cyclically shifting property of IFFT is used which doesn’t require side information for the transmission. With this technique the complexity has been reduced in comparison with the conventional partial transmit sequence and the PAPR reduction performance is improved with increase in the number of sub-blocks M due to increase in the number of values.
