Abstract

The development process involved developers contribution based his/her cognitive thinking in
the real time process. The developer's performance is dynamic as per their cognitive
load. The cognitive load is un-deterministic as well hidden and integrated in the
developer's process. This paper attempt to identify software developer cognitive
measure which influences the development process using neural network back propagation
model. It describes the conceptual view on conventional construction of neural network for
cognitive measure observation of software development processes. A neural network model
designed to present the structure of developer's performance such as Regularity, Task
Completion, Accuracy, Team Involvement and Reporting are used to generate the Performance
and Cognitive Load of the output layer. To obtain the Performance and the Cognitive Load from
the given input, the Cognitive work load such as physical ability, mental ability, temporal ability,
effort, frustration and performance are assigned to a hidden layer. The observation and the
results are described and discussed as part of the paper.
