Abstract

Outlier detection can be viewed as a classification problem if a training data set with class labels is available. Generally, in a typical medical dataset such as a cancer data set, if there are samples available with class information, then it is possible to apply a classification based outlier detection method. The general idea of classification-based outlier detection method is to train a classification model that can distinguish normal data from outliers [7]. Previous work had implemented and evaluated using the three classifications based outlier detection algorithms and found that the k-neighborhood algorithm was capable of identifying and classifying the outliers better than the other two compared algorithm in terms of accuracy, f-score, Sensitivity/Recall, error rate. Further, the cpu time of the k-neighborhood algorithm also minimum [23]. In this work, the performance of outlier detection using feature selection algorithms are evaluated but the results clearly shows that the impact of feature selection algorithm on the cancer dataset is very low and does not improve the overall classification performance.
An Analysis on the Performance of a Classification based Outlier Detection System using Feature Selection
