Abstract

Frequent Itemset Mining (FISM) finds the large and frequently occurring items from the datasets using Apri-ori algorithm. The FISM framework does not address two major properties that are Mixture-of property (more than one customer intent) and Projection-of property. To overcome the problems of irrelevant and non actionable data and also to address the properties mentioned above, Logical Itemset Mining (LISM) framework is introduced. LISM not only finds logically connected items but also items which are rarely occurring but logically connected are also discovered. LISM also addresses the Mixture of property and Projection of property which are not very well addressed in FISM.
