ABSTRACT

Despite the advantages of utilizing hospital information systems (HISs) in nursing care, and their contribution to nursing structures and care processes, the troubling issue of HIS underutilization continues. Low utilization of installed systems has been identified as a major problem in implementing information technology (IT). Unfortunately, nurses have been unwilling to apply technology to healthcare delivery, although they generally have a positive attitude toward computers. In this study, based on the Critical Success Factors (CSFs) and DeLone and McLean's Information Systems success model, an implementation framework, made up of essential elements to guide successful HIS implementation for nursing staff is proposed. This study is among the few that have tested empirically an implementation framework in the developing countries settings, and provides helpful guidelines for hospital managers in planning HIS implementation in such countries.

General Terms

Critical success factors, Hospital Information System, Success model, DeLone and McLean.

Keywords

Hospital Information System, Success model, Information culture, Organization culture, trust, developing countries.

1. INTRODUCTION

Information systems (IS) are used by organizations to store, filter and process data (Wikipedia). Hospitals are investing a large amount of money on HIS to get benefits from these systems. Since large investments are made in IT, the organizations are interested in knowing the success of these systems and want to find out the impact of these systems on them as well as on individuals.[1] The effectiveness of these systems depends upon many factors like organizational, environmental and people who use them [2]. It is not easy to evaluate the success of information systems so measuring IS success is of utmost importance. It is a multidimensional concept that can be evaluated at various levels [3].

Malik and Khan [4] have suggested that for leading successful implementation of IS in any organization there must be some change process. They have explained that the developing countries are facing problems to get benefits of IS. Overall, the success rate of HIS implementation is very low in

developing countries [5-6]. There are scarce examples on successful implementation of HIS in developing countries as compared to developed countries. The studies from the developed countries can't be utilized as guideline for the implementation process in developing countries because in both, the working culture and circumstances are different. Therefore a new model is designed to provide a new HIS implementation framework which may include the cultural characteristics of each individual hospital and could hopefully be successfully implemented in the health organizations of the region.

2. REVIEW OF LITERATURE

2.1 HIS

Hospital Information System (HIS) is considered as an important factor in health care sector for managing the administrative, financial and clinical aspects of a hospital. A large number of hospitals from both developing and developed countries are adopting hospital information system to bring efficiency in their current system [7].

During the last few decades health care managers have tried to maximize hospitals' productivity, without reducing the quality of health care services provided to the patients [8-10].

Recent literature suggests that the adoption of Health information system in hospitals can improve information and service integration, communication, and coordination among clinicians [11-14], health care quality and safety [15], reduce costs [16], control resource allocation, increase service efficiency and productivity, and enhance service availability, quality, and satisfaction for patients and health care providers [17-19]. HIS may also improve health care quality through the use of standardized clinical pathways; e-prescribing systems, which would detect drug interactions; and better and more complete documentation of care [14]. These improved processes are expected to lead to significant reductions in medical errors [20-21]. The automated access of physicians to patient laboratory and other diagnostic results may reduce lost orders and errors due to illegible handwriting, and minimize duplicate orders [22], thus improving health care quality outcomes and efficiency [23]. Patient satisfaction as an outcome indicator of health care delivery has been widely accepted as a significant indicator for measuring quality of health care and as a critical component in performance improvement and clinical effectiveness [11, 24-25].

from all-over the world were collected and considered to be expert panel in this research.

3.4 The instrument

The questionnaire consisting of ten main constructs and multiple relevant measures was electronically mailed to all of the one hundred authorities with a letter describing the purpose of the investigation and asking their kind participation and prompt answer. The questionnaire was designed to get the viewpoints of experts regarding the major constructs affecting the success of HIS implementation. A Likert scale was used (Table 1). Experts were asked to score each item from 1 to 7 based on their perception regarding the significance of any particular parameter. A score of “0” was considered as “no answer”.

Table 1: Showing the 7-point Likert response scale for assessment of the expert views on the effectiveness of the constructs and their measures on the successful HIS implementation

Construct	Measure	Effect on successful HIS implementation						
		Not important at all	Not important	Not effective	Rarely important	Sometimes important	Frequently important	Always important

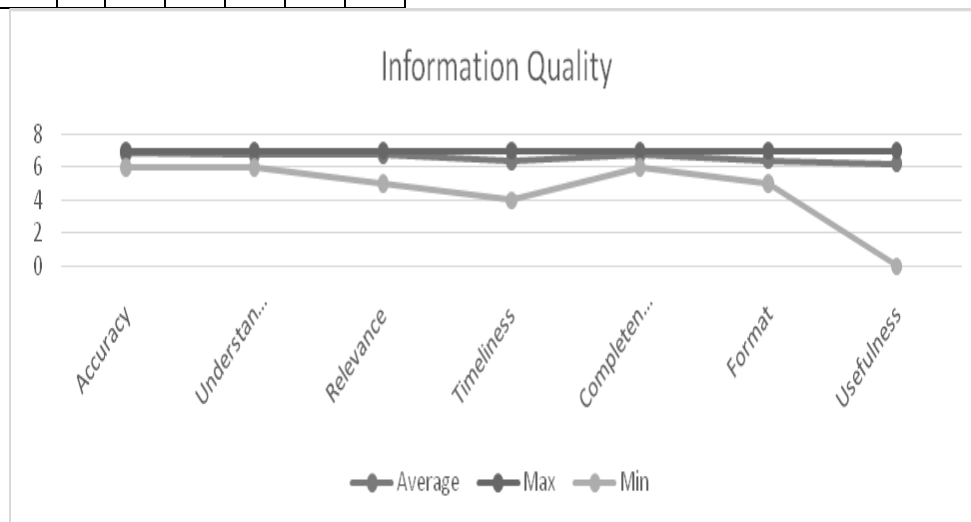

Figure 2: Showing the maximum, minimum and average scores of measures regarding the information quality construct

Table 2: The scale content validity index (S-CVI) of the ten constructs used for the proposed HIS success model

Construct	S-CVI/AVE	Accepted	Rejected
User Quality	0.80	√	
System Quality	0.96	√	
Information Quality	0.94	√	
Service Quality	0.89	√	

3.5 The content validity index

The content validity index for scales (S-CVI) [51] was used to assess the experts’ responses regarding the relevance of each item (measure) with the appropriate construct being evaluated. As stated by Polit and Beck [52], content validity index can be defined as “... the degree to which an instrument has an appropriate sample of items for the construct being measured”. Actually content validity is concerned with the degree to which a group of items, taken together, constitute an adequate operational definition of a given construct. A $S-CVI \geq 0.8$ was considered acceptable [53].

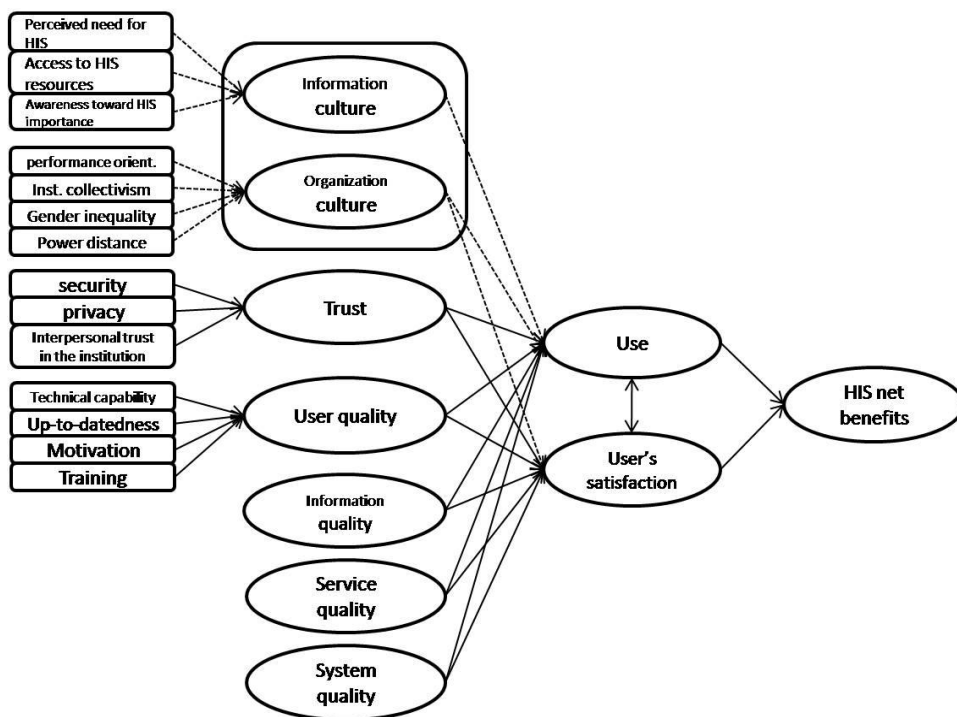

4. RESULTS

Overall 21 experts responded back via email. Of the 10 constructs, 9 were approved and 1, the social influence, was rejected (Table 2). But the newly added constructs, the information culture, the organization culture as well as trust and user quality were strongly selected (Table 2).

Figure 2 shows the graphic demonstration of the expert's responses regarding the information quality construct.

Putting all available selected and validated constructs, dimensions and parameters the following HIS success model was proposed (Figure 3).

Intention to use/ Use	0.92	√	
Trust	1.00	√	
Social influence	0.77		√
Culture (information and organization)	0.83	√	
User satisfaction	0.88	√	
Net Benefit	0.88	√

5. DISCUSSION

A new HIS implementation success model basically derived from the constructs and success items selected and approved by a group of 21 experts. The DeLone and McLean's IS success model constitute the major body and framework of new model.

Since the DeLone and McLean's model can provide a good framework to identify and develop different measures for several important dimensions, it could also be used in the field of human-centered technology to understand different aspects of IS success. Both the original and updated models have been based on literature reviews and many researchers have tried to validate, use and develop these models further. However, instead of having ready-to-use measures, there is a lot of work to be done when modifying the model for own purposes, and this is what has been done in the present work too.

Health care systems are investing a large amount of money on HIS and are interested in knowing the success or failure of these systems. Therefore, the benefits of the HISs require frequent and rigorous evaluation. It is said that organizational and social issues are the main components of such a system [54]. The more technology, human and organization fit with each other, the greater would be the productivity of HIS. Most existing evaluation studies of HIS focus on technical issues or clinical processes, which do not explain why HIS works well or poorly with a specific user in a specific setting [55]. Hence it becomes important as well as necessary to develop and present various IS success models.

Baus [56] explains that in some cases the organizational nature of HIS implementation is more important than its technical components. HIS can modify the working relationships between the people working in the hospital and

it has positive effect on the ways in which hospital staff work together provide health care, and carry out their daily work practices. According to Wager et al. [57] the impact on the organizational structure must be understood before the successful implementation of HIS.

Since the HIS assists healthcare providers to streamline the flow of patients' information and its accessibility, the significance of the HIS in providing high quality patient care has grown [58]. Therefore, implementation of HIS becomes fundamentally essential in meeting associated diagnostic, treatment and administration requirements, and thereby in delivering better patient care and support to clinical decision making [59]. The HIS has clearly led to a change in the process of care delivery, and has helped to improve the quality and safety of care [29, 58, 60-62]. However, compared to other technologies in the healthcare domain, the acceptance level of HIS is still low [63-64].

An IS may fail or it can be successfully implemented in any environment. In both developing and developed countries, the research contains success and failure issues [65]. Human and financial barriers have been found to be two major categories of barriers challenging in the way of successful HIS implementation in the developing countries [66].

Other than selecting a research [67] topic and an appropriate research design, research method is considered to be another major component since it specifies the forms of data collection, analysis and interpretation [67]. The forms of data collection are questionnaires, interviews and observations. The choice of methods is largely governed by the purpose of the study, time constraints, available budget and resources, so that the method's bias can be addressed [68-69].

According to Ridder [70], data collection for qualitative research include many ways like reviewing documents, archival records, interviews, direct observation and participant observation. Interviews are used to get deep understanding of participant's views and ideas regarding the research questions. As Creswell [67] stated, by conducting interviews, most relevant and accurate data could be collected for research purposes. Interviews can be conducted as face to face interaction, online interaction, email interaction, or phone interaction.

As the number of the critical success factors and measures to develop the proposed success model as well as the number of the experts were too many, the electronic mail method was used since it needed only a one time set up, and was much cheaper and faster than other data collection methods.

6. CONCLUSION

Here a new HIS implementation success model has been proposed for the nursing staffs of hospitals in the developing countries. It is clear that because of cultural and economical differences the model from developed countries can't be utilized as proper guidelines for HIS implementation in developing countries. Therefore, it is hoped that this model would help the successful implementation of HIS in the health care organizations of the region.
