## ABSTRACT

Artifacts cause the error in reading of ECG signals. The artifacts like PLI, Baseline wander, Electromyogram are introduced and hence removal of these artifacts is an important task in biomedical science. Adaptive filtering algorithms are evolving rapidly to eradicate noise. In this paper, the RLS technique in comparison with the LMS technology to remove the noise from the ECG signal is proposed. RLS algorithm is applied to the real ECG signal, collected from the MIT BIH database. The comparison will be done based on minimum mean square error, PSNR and coefficient correlating factor. Since, the RLS algorithm shows typically fast convergence as compared to LMS algorithm. From the result it is concluded that RLS based algorithm performance is superior to that of LMS based algorithm.

## Keywords

Adaptive filter, ECG, RLS, LMS, PSNR, MMSE, PLI

## 1. INTRODUCTION

Electrocardiography is the process of recording the electrical activity of the heart over a period of time using electrodes which are placed on the skin the electrical changes on the skin that are generated from the heart muscle's electro physiologic pattern of depolarizing during each heartbeat. The magnitude of the heart's electrical potential is measured and is recorded over a period of time; the usual duration is of 10 seconds. The graph of voltage versus time produced is termed as electrocardiogram. [1]

Electromyogram, instrumental noise, motion artifacts. The causes of interference are explained by James et al. in [2]. The segregation of high resolution ECG signal from this contaminated signal is an important issue to investigate. There are various techniques which have been used for artifacts rejection from ECG. Conventional filters remove the artifacts up to some extent but these filters are static filters. These filters cannot update their coefficients with change in environment. Adaptive cancellers are used to handle non-stationary signals. The adaptive filter can adjust the filter coefficients according to the adaptive algorithm Syed Rehman et al [3].

For the removal of noise from ECG a comparison between most commonly used filters techniques like Notch filters, FIR filters, IIR filters, Wiener filter, Adaptive filters algorithms LMS, NLMS, DLMS etc. is proposed in Rajesh Wagh et al [4]. The different adaptive filter algorithms LMS, RLS, NLMS are compared on the basis of implementation aspects, computational complexity and signal to noise ratio. It proves that the RLS algorithm is best to eradicate the noise in terms of improved SNR,

MMSE by Jyoti et al [5]. Kalman based least mean square filter is proposed by M. Sushmitha et al [6] for the removal of power line interference from the ECG signals. Kalman filter minimize the mean square error and removes the PLI. Here the operation principal of Kalman filter is described. The analysis of the performance of LMS and NLMS based adaptive filters design and simulation is presented where noise is removed by adaptive algorithm by establishing correlation between noise and its estimated value Divya et al [7].

Patch based method for rejection of artifacts from ECG signals but at the cost of computational complexity and slow convergence coefficient is described by Akansha Deo et al [8]. Discrete Wavelength Transform is used to eliminate 50HZs PLI from the signal and comparison is made with the Butterworth IIR notch filter. The proposed method has an effect of wavelet thresholding on the ECG reconstruction where an IIR notch when applied to ECG shows ringing effect. HAAR wavelet transform remove the noise but changes the shape of reconstructed waveform which prove that Daubechies Db4 wavelet transform method is best Prajakta S Gokhale et al [9]. A survey of different techniques used for the noise removal is studied where a comparison between Finite impulse response filter with different window and an Infinite impulse response filter is used for the removal of noise. The result indicates that Kaiser Window based FIR filters is having maximum efficiency Bhumika et al [10].

As biomedical signals are affected by noise a design of adaptive filter with a dynamic structure is explained. The dynamic filter in the first step decreases the error drastically and as the adaptation count increases error decreases as a function of logarithm. DSAF performs better as proposed by Ju-Won Lee et al [11].

A delayed LMS algorithm is proposed which is mostly implemented in hardware with performance degradation is not acceptable, a correction term is added but it increases the power consumption. To over this problem a retiming DLMS architecture is used and which result in responsive and less degradable system B. V, Hood et al [12].

For the denoising an NLMS algorithm is applied. The paper describes comparison between the method implemented previously and the proposed method. To cope with the complexity and convergence issues without any restriction tradeoff modified NLMS algorithm is proposed for the removal of noise from ECG Smita Dubey et al [13]. When input signal is stochastic then Least Mean Square algorithm gives good performance but for deterministic input signal Recursive Least Square algorithm gives better performance than LMS algorithm. In this paper we proposed an efficient RLS algorithm for

the removal of noise. For the validation of the system the corrupted signal is passed through the LMS filter. Result analysis shows that RLS algorithm given better result compared to the LMS algorithm in terms of PSNR, MMSE and correlation coefficient.

## 2. ADAPTIVE FILTER AND RLS ALGORITHM

An adaptive filter modifies its frequency response automatically to improve the performance with some criteria as shown in Figure1.

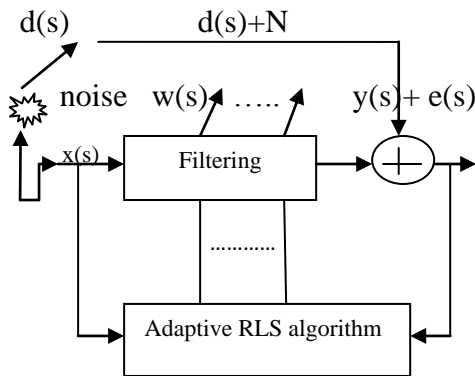

Fig.1. Adaptive filter structure with RLS algorithm

Due to its property to adjust to the changing environment adaptive filters are used in wide applications. Adaptive filters change the coefficients of digital filter. LMS and RLS are basic algorithms. The LMS algorithm does not require the past information of the signal characteristics but provides filter coefficient estimation which progresses with time. The RLS is based on the steepest descent algorithm which changes its weight vector coefficient from sample to sample. It has a fast convergence rate and shows better performance. The coefficients of the RLS algorithm are as given.

$$W(n+1) = W(n) + e(n) \cdot k(n) \quad (1)$$

Where  $w(n)$  is the filter coefficient vector,  $k(n)$  is the gain factor,  $e(n)$  is the error signal.

$k(n)$  is given as

$$k(n) = \frac{p(n) \cdot u(n)}{\lambda + u^t(n) p(n) \cdot u(n)} \quad (2)$$

$\lambda$  is the forgetting factor and  $p(n)$  is the inverse correlation matrix and given as

$$p(n) = \delta^{-1} u(n) \quad (3)$$

Where  $\delta$  is the regulation factor and  $u(n)$  is the unity matrix. The inverse correlation matrix in the RLS algorithm is updated by [4]  $eq^n$

$$P(n+1) = \lambda^{-1} (P(n) - \lambda^{-1} k(n) u^t(n)) \cdot P(n) \quad (4)$$

To adjust the RLS algorithm parameter one has to adjust the forgetting factor. The forgetting factor lies in the range of 0 to 1 and the initial value of the inverse correlation matrix is the regulation factor.

## 3. SIMULATION RESULT DISCUSSION

The analysis of the system is performed on the MATLAB tool. The pure ECG signal which is applied as an input to the filter can be generated from the MATLAB function of desired length or it can be collected from the MIT-BIT Physionet database. The database contains 47 subjects' ECG signal data. The data is collected from men and some of them are collected from women. Three records (109, 208, 214) are randomly collected from 47 subjects. These signals are sampled at 360 Hz, 11-bit over a 10 mV range of resolution. Then this noise-free ECG is applied as an input and added with one of the noise sources such as PLI, baseline wander, and electrogram. This is in turn applied to the adaptive filter as shown in Fig. 2. The PLI is considered as noise which is added to the ECG while acquiring the ECG. This noise completely corrupts the original ECG signal, so it should be removed for accurate diagnosis. For the removal of noise, it should be applied to the above-mentioned adaptive algorithms. Fig. 4(a) shows the original ECG signal. Then to this PLI is added as shown in Fig. 4(b) for 1450 samples. For the removal of noise, an LMS algorithm is applied. Fig. 4(c) shows the denoised signal obtained after LMS filtering, and a plot of the minimum mean square error is obtained in Fig. 4(d). For the same record and for the same value of number of samples, the RLS algorithm is applied to it, and the graph is obtained in Fig. 4(e) along with the MU plot in Fig. 4(f). From Fig. 4(c) it is observed that some amount of noise is still present, but by using the RLS algorithm, this noise is removed almost. In the following figures, the x-axis takes the number of samples and the y-axis represents the amplitude. The same procedure is applied for the baseline wander and electrogram; outputs are obtained as plotted in Fig. 5(a-f) and Fig. 6(a-f) respectively. The PSNR obtained for the LMS and RLS algorithms for PLI, baseline wander, and electrogram are estimated as shown in Table I. The performance characteristics in terms of MMSE and execution time are shown in Table II.

## 4. CONCLUSION

The proposed adaptive RLS technique gives an optimum quality of ECG signal. This paper mainly concentrates to reduce PLI, baseline wander, and electrogram using RLS-based adaptive filters. The comparison of the proposed technique is made with the LMS algorithm. The performance analysis of the signal is done in terms of PSNR, MMSE, and convergence rate. From the above analysis, the RLS algorithm gives better reduction of noise compared to the LMS algorithm. The future development to this work can be made by the implementation of wavelet-based denoising for the removal of baseline wander and real-time application of implemented algorithms.

**Table 1: PSNR obtained after applying LMS and RLS algorithms**

Algorithm	Noise	PSNR before filtering	PSNR after filtering
LMS	PLI	30	35.5209
RLS		30	43.5292
LMS	Baseline wander	30	36.9090
RLS		30	43.2813
LMS	Electromyogram	30	38.7472
RLS		30	38.9615

**Table 2: MMSE and EXECUTION TIME obtained after applying LMS and RLS algorithms**

Algorithm	Noise	MMSE	TIME of execution in sec
LMS	PLI	0.0002805	0.00156
RLS		0.0004437	0.008681
LMS	Baseline wander	0.00020375	0.001510
RLS		0.00004697	0.007139

LMS	Electromyogram	0.000133	0.001497
RLS		0.00012701	0.006909
