ABSTRACT
An exact solution of the vacuum Einstein field equations (VEE) has been obtained of a spatially homogeneous and anisotropic (SHA) Bianchi type-I cosmological model by Kasner. The Kasner metric is shown to be a special case, and the exact vacuum solution of Kasner form model is obtained. Some physical properties of the model have been discussed.

AMS Subject Classification: 83D05, 83F05, 83C15.

Keywords  
Bianchi type-I, Vacuum solution, Cosmological model, Kasner form

1. INTRODUCTION
The simplest models are the Bianchi type-I cosmologies in class A with \( n^{(1)} = 0 \), i.e. \( C_{i}^{j}k = 0 \), where \( n^{(1)} \) is the parameters various symmetry types with values 0, ±1 and \( C_{i}^{j}k \) are the structure constants of the Lie algebra of the homogeneity group. So that all three Killing vectors (the group generators) commute. They contain the standard Einstein de-Sitter model with flat spatial hyper-surfaces (curvature index \( k = 0 \)). In the vacuum case, all Bianchi type-I models are given by the well-known 1-parameter family of Kasner metrics (found in 1921 by E. Kasner and in 1933 by G. Lemaître without considering the Bianchi groups) [1].

The Kasner space-time is an exact solution of the VEE \( R_{ij} = 0 \), and the solutions play an important role in the discussion of certain cosmological questions. In another way, the Kasner solutions are obtained if the energy-momentum tensor \( T_{ij} \) vanishes and the isometry group on spatial slices is the trivial one. Deruelle and Sasaki 2003 [2] were considered the Kasner metrics in the Gaussian-Bonnet case.

The purpose of this paper is to obtain an exact solution of the vacuum FE from a SHA Bianchi type-I cosmological model. The well-known Kasner solution is obtained as a particular case.

2. BIANCHI TYPE-I COSMOLOGICAL MODEL
Let us consider the simplest vacuum SHA Bianchi type-I cosmological solution. This is the so called Kasner solution. The metric of Bianchi type-I is given by [3]

\[
ds^2 = dt^2 - \sum_{i=1}^{3} A_i^2(t) dx_i^2, \tag{1}
\]

where \( A_i, i = 1, 2, 3 \) are functions of time \( t \) which are called cosmic scale factors [3]. Note that if \( A_1 = A_2 = A_3 = \alpha \) we encounter the Friedmann-Robertson-Walker (FRW) solution with \( k = 0 \). The computations of the Ricci tensor \( R_{ij} \) and its spur using Mathematica [4] and [5]; the non-vanishing components are,

\[
R_{11} = -\dot{H}_1 - \theta H_1, \tag{2}
\]

\[
R_{22} = -\dot{H}_2 - \theta H_2, \tag{3}
\]

\[
R_{33} = -\dot{H}_3 - \theta H_3, \tag{4}
\]

\[
R_{44} = \dot{\theta} + H_1^2 + H_2^2 + H_3^2, \tag{5}
\]

where an overhead dot denotes derivative with respect to time \( t \) and \( H_1, H_2, H_3, \theta \) are the directional Hubble parameters (HPs) in the direction of \( x_1, x_2, x_3 \) and scalar expansion respectively gives

\[
H_1 = \frac{\dot{A}_1}{A_1}, \quad H_2 = \frac{\dot{A}_2}{A_2}, \quad H_3 = \frac{\dot{A}_3}{A_3} \quad \text{and} \quad \theta = H_1 + H_2 + H_3. \tag{6}
\]

The energy -momentum conservation condition is of the following form

\[
\dot{\rho} + \theta (\rho + p) = 0, \tag{7}
\]

where \( \rho \) is the proper energy density and \( p \) is the isotropic pressure. Because it’s consider the vacuum solution, \( T_{ij} = 0 \). The EFEs are given by

\[
R_{ij} - \frac{1}{2} R g_{ij} = 0, \tag{8}
\]

where the corresponding Ricci scalar \( R \) is given by

\[
R = 2 \left[ H_1 H_2 + H_2 H_3 + H_1 H_3 + \theta + \theta^2 \right]. \tag{9}
\]

The “44” component of the Einstein field Equations [6] for the metric [1] lead to

\[
R_{44} - \frac{1}{2} R = -[H_1 H_2 + H_2 H_3 + H_1 H_3] = 0. \tag{10}
\]

As the result at Equation (10), from the definition of \( \theta \) it’s found that

\[
\theta^2 = (H_1 + H_2 + H_3)^2 = H_1^2 + H_2^2 + H_3^2. \tag{11}
\]
Hence, using Equation (11) in Equation (5), we get
\[ R_{11} = \theta + \theta^2 = 0. \tag{12} \]
If \( \theta = 0 \), Equation (11) implies that \( H_1 = H_2 = H_3 = 0 \), i.e., \( A_1 \), \( A_2 \) and \( A_3 \) are constants. This gives Minkowski space-time.

If \( \theta \neq 0 \) the differential Equation (12) can be solved by separation of variables,
\[ \theta = \frac{1}{1 - t_0}, \tag{13} \]
By a choice of the origin it can be set \( t_0 = 0 \). Then
\[ R_{11} = -\dot{H}_1 - \theta H_1 = 0, \tag{14} \]
Solving Equation (14), we get
\[ H_1 = \frac{p_1}{t}, \tag{15} \]
for some constant \( p_1 \). Similarly by using Equations (3) and (4), we obtain respectively
\[ H_2 = \frac{p_2}{t}, \quad \text{and} \quad H_3 = \frac{p_3}{t}, \tag{16} \]
for some constants \( p_2 \) and \( p_3 \). So the Equations (11), (13) and (16) with (6) imply that \( \theta = \frac{1}{t} = H_1 + H_2 + H_3 = \frac{p_1}{t} + \frac{p_2}{t} + \frac{p_3}{t} \), we get
\[ \sum_{i=1}^{3} p_i - \sum_{i=1}^{3} p_i^2 = 1. \tag{17} \]
These are known as the Kasner relations. Now from \( H_3 = \frac{p_3}{t} = \frac{\dot{H}_3}{t} \) we obtain that \( A_1 = A_0 t_0 \) and similarly for \( A_2 \) and \( A_3 \). Thus, the Kasner’s metric can therefore be written as
\[ ds^2 = dt^2 - \sum_{i=1}^{3} t^{2p_i} dx_i^2, \tag{18} \]
after the appropriate rescalings of \( x_i \), \( i = 1, 2, 3 \). Here \( p_i, \ i = 1, 2, 3 \) are subject to Equation (17).

The Kasner metric (18) is a solution to the VEEFs, thus Ricci tensor \( R_{ij} \), Ricci scalar \( R \) and its spur identify vanishes for any choice of exponents satisfying the Kasner conditions. The full Riemann tensor vanishes only when a single \( p_i = 1, \ i = 1, 2, 3 \) and the rest vanish, in which case the space is flat.

For \( t > 0 \) the Kasner metric metric (18) describes an expanding homogeneous anisotropic universe, while for \( t < 0 \) the contracting universe.

The exponents \( p_i, \ i = 1, 2, 3 \) which is called the Belinskii, Khalatnikov, and Lifshitz (BKL) in the 1960’s and 70’s [6, 7, 8] parameterization can be parametrized by a real variable \( u \geq 1 \). Suppose without loss of generality that \( p_1 < p_2 < p_3 \), then
\[ p_1(u) = \frac{-u}{1 + u + u^2}, \tag{19} \]
\[ p_2(u) = \frac{1 + u}{1 + u + u^2}, \tag{20} \]
\[ p_3(u) = \frac{u(1 + u)}{1 + u + u^2}, \tag{21} \]
as the parameter \( u \) varies in the range (see Figure 3)
\[ 1 \leq u < +\infty. \tag{22} \]

Figure 1 is a plot of \( p_i, \ i = 1, 2, 3 \) versus parameter \( \frac{1}{u} \). The numbers \( p_1(u) \) and \( p_3(u) \) are monotonously increasing while \( p_2(u) \) is monotonously decreasing function of the parameter \( u \).

The parameterization for \( u < 1 \) leads to the same range by following the inversion property
\[ p_1 \left( \frac{1}{u} \right) = p_1(u), \tag{23} \]
\[ p_2 \left( \frac{1}{u} \right) = p_3(u), \tag{24} \]
Fig. 2. The plot of Kasner indices $p_i$, $i = 1, 2, 3$ versus parameter $\frac{1}{u}$.

$$p_3\left(\frac{1}{u}\right) = p_2(u).$$  \hspace{1cm} (25)

Figure 2 is a plot of $p_i$, $i = 1, 2, 3$ versus parameter $\frac{1}{u}$. The numbers $p_1(u)$, $p_2(u)$ and $p_3(u)$ are monotonously increasing and decreasing function of the parameter $u$.

The quantity $p_1 p_2 p_3$ is typically replaced by the Kasner parameter $u$ through

$$p_1 p_2 p_3 = \frac{-u^2 (1 + u)^2}{(1 + u + u^2)^3}, \quad u \in [1, \infty).$$ \hspace{1cm} (26)

Looking for explicit values of those exponents one finds that except for the solutions with one index $p_i = 1$, $i = 1, 2, 3$ the others vanish, which could be proved in correspondence with the Minkowsky space solution (MSS) the Kasner indexes must be distributed in the following way

$$-\frac{1}{3} \leq p_1 \leq 0, \hspace{1cm} (27)$$

$$0 \leq p_2 \leq \frac{2}{3}, \hspace{1cm} (28)$$

$$\frac{2}{3} \leq p_3 \leq 1. \hspace{1cm} (29)$$

The Equations (19), (20) and (21) imply that except for the two sets of Kasner exponents $(1, 0, 0)$ or $(2, -1, -1)$ and $(\frac{2}{3}, \frac{2}{3}, \frac{2}{3})$, all other sets of exponents contain one negative number and two positive numbers which are all different. The Kasner metric belongs to the homogeneous Bianchi type-I classification of the metric.

We come back to the spatial form of the Kasner metric (17) and (18), one sees that the requirement of symmetry in the plane between the $x_2$ and $x_3$ directions implies the condition

$$p_2 = p_3. \hspace{1cm} (30)$$

Figure 3 is a plot of $p_i$, $i = 1, 2, 3$ versus parameter $\frac{1}{u}$. The domain of $u$ is $[1, \infty)$; for lower values of $u$ the inversion property (23), (24) and (25) holds. The numbers $p_1(u)$ and $p_2(u)$ are monotonously increasing while $p_3(u)$ is monotonously decreasing function of the parameter $u$.

It is easy to see that there are two solutions of Equation (17) which satisfy the condition (30).

2.1 Flat space-time

The flat space-time should be noted that with

$$p_1 = 1, \hspace{0.2cm} p_2 = p_3 = 0. \hspace{1cm} (31)$$

In this case, the metric becomes

$$ds^2 = dt^2 - t^2 dx_1^2 - \sum_{i=2}^{3} dx_i^2. \hspace{1cm} (32)$$

which can be transformed to a metric of a flat space using a coordinate transformation. Due to this reason, the Kasner metric with any of the Kasner exponents unite and the others vanish is called the flat Kasner metric. The classical flat Kasner space-time has a non-curvature singularity at $t \to 0$.

This case was given by Taub (1951) [9], other rediscoveries were listed by Harvey (1990) [10]. It is well-known that the Rindler space-time [11] represents a part of the Minkowski space-time rewritten in the coordinates connected with an accelerated observer by the transformation

$$t \ sinh \ x^3 = \xi, \hspace{0.2cm} t \cosh \ x^3 = \tau. \hspace{1cm} (33)$$

It is worth noting that in this particular case. There is a coordinate singularity at $t \to 0$.

It's conclude that in the Bianchi type-I cosmology, which corresponds to a flat but anisotropic universe, there are three different scale factors referred to the spatial axes with two of them that increase with time and one which conversely decreases.
2.2 Non-flat space-time

The non-flat plane symmetric should be noted that with

\[ p_1 = -\frac{1}{3}, \quad p_2 = p_3 = \frac{2}{3}. \]  

In this case, the metric becomes

\[ ds^2 = dt^2 - t^{\frac{2}{3}} dx_1^2 - t^{\frac{4}{3}} \sum_{i=2}^{3} dx_i^2. \]

This particular solution was found by Weyl [12] and Levi-Civita [13] before the work of Kasner. This solution describes a universe, where a real curvature singularity is present at \( t \to 0 \).

3. PHYSICAL AND GEOMETRICAL PROPERTIES OF THE KASNER MODEL

The average scale-factor \( a(t) \), and spatial volume \( V \) are given by,

\[ V = \sqrt{-g} = a^3 = t^{p_1 + p_2 + p_3} = t. \]

Note that the spatial volume \( V \) of a Kasner metric grows with time \( t \) in the limit \( t \to 0 \) we have a Big-Bang (BB) like singularity and vanishes at \( t = 0 \). It expands exponentially as \( t \) increases and becomes infinitely large as \( t \to \infty \).

The mean HPs, deceleration parameter (DP) and scalar expansion \( \theta \) are

\[ H = \frac{\dot{a}}{a} = \frac{1}{3t}, \]
\[ q(t) = -\frac{\ddot{a}}{aH^2} = 2, \]
\[ \theta = 3H = \frac{1}{t}. \]

Those do not depend on the supremacy of any of the axis. The directional HPs in the direction of \( x_1, x_2 \) and \( x_3 \) are obtained as

\[ H_i = \frac{p_i}{t}, \quad i = 1, 2, 3 \ (no \ sum). \]

We observed that the HPs, directional HPs, and scalar expansion start with infinite value at \( t = 0 \) and then become constant (decreasing function of time \( t \) after some finite time \( t \)).

The shear scalar \( \sigma^2 \), and the average anisotropy parameter \( \bar{A} \), which are defined as

\[ \sigma^2 = \frac{1}{2} \left[ \sum_{i=1}^{3} H_i^2 - 3H^2 \right] = 0, \]
\[ \bar{A} = \frac{1}{3} \left[ \sum_{i=1}^{3} \left( \frac{H_i - H}{H} \right)^2 \right] = 2 \neq 0. \]

The average anisotropy parameter \( \bar{A} \neq 0 \) is constant throughout the evolution of the universe, which implies that the Kasner model is anisotropic.

The shear parameter is given by

\[ \Sigma^2 = \frac{\sigma^2}{3H^2} = 0 \]

The shear scalar \( \sigma^2 \) and shear parameter is zero throughout the evolution of the universe.

4. CONCLUSION

Exact vacuum solution of the Kasner metric from Bianchi Type-I models is obtained. The Kasner metric from Equation (18) describes an anisotropic space where volumes \( V \) linearly grow with time, while linear distances grow along with two directions and decrease along the third one, different from the FRW solution where all distances contract towards the singularity with the same behavior. This metric has only one non-eliminable singularity in \( t = 0 \) with the single exception of the case \( p_1 = 1, \quad p_2 = p_3 = 0 \) mentioned above, corresponding to the standard Euclidean space.
