Abstract

A dominating set $D$ of a graph $G = (V;E)$ is non-split dominating set if $hV \cap D$ is connected. The non-split domination number of $G$ is the minimum cardinality of a non-split dominating set in $G$. Let $D$ be a minimum dominating set in $G$. If a subset $D'$ of $V \cap D$ is dominating in $G$, then $D'$ is called an inverse dominating set with respect to $D$. Furthermore, if $V \cap D'$ is connected, then $D'$ is called an inverse non-split dominating set. The inverse non-split domination number of $G$ is the minimum cardinality of an inverse non-split dominating set in $G$. In this paper, characterization of non-split dominating sets in the join and corona of two graphs are presented. Furthermore, explicit formulas for determining the non-split and inverse non-split domination numbers of these graphs are also determined.
