Abstract

Isomeric pterocarpsans, Dolichin A and Dolichin B of *Macrotyloma uniflorum* were docked with the three replication enzymes of HIV (Reverse transcriptase, Protease, Integrase). Analysed results proved that the docking score was high for Protease with Dolichin A (-6.6899) and Dolichin B (-6.6944) among Reverse transcriptase and Integrase. AIDS therapies could be scrutinized and/or replaced after the successful inhibitory effect of Dolichin. This study will support the cutting edge of HIV research and drug designing to find out a less side effect causing herbal formulations.
