ABSTRACT

In this paper we propose to attach radio frequency (RF) shields on mobile phone to reduce Specific Absorption Rate (SAR) in the spherical head model. Shields made of ferrimagnetic materials are used to suppress surface currents on the mobile phone. Many kinds of simulation are performed to investigate the effect of various parameters like location, size, shape and thickness of the shield on the SAR and also on the antenna performance using the field simulation software, CST-Microwave studio (MWS). Paper includes numerical evaluation of the SAR reduction in the spherical head model and also analyzes the SAR data for shielding effectiveness.

Keywords

SAR, SRF, Mobile phone, Radiation pattern, Ferrimagnetic materials, RF shields.

1. INTRODUCTION

Mobile phone safety remains a topic of growing public concern. There are two issues concerning mobile phone safety. The first is that of non-thermal biological effects. These effects are related to the amount of RF energy deposited in the tissue – RF dosimeter [1]. The second is that of computational RF dosimetry. Computer simulation is used to estimate the deposition of RF energy, the SAR, in the head of a user. The SAR [2] in the human head is defined as

$$SAR = \frac{\sigma |E|^2}{\rho} w / kg \quad (1)$$

Where σ is the electrical conductivity of tissue, E is the rms magnitude of the electric field strength vector at a given point in the head model, and ρ is the mass density of tissue. The SAR is normally used to evaluate the degree of the hazard to the human body. As per the FCC, ANSI/IEEE and Safety code 6 standards the recommended SAR values are 0.08 W/Kg for a Whole body and 1.6W/Kg for over any 1gram of tissue. Because live human heads can not be safely experimented for these measurements, computational RF dosimetry provides the best estimate of SAR in actual human heads. There is a need to develop techniques for reducing SAR in the design stage of mobile phone to meet exposure standards [3].

One way of reducing SAR in the human head is by attaching RF shield made of a ferrimagnetic material to the front side of the mobile phone [4]. The mechanism behind reduction of SAR is due to the suppression of surface currents on the front side of mobile phone box. When an electromagnetic wave (EMW) traveling through free space encounters a different medium, the

wave will be reflected, transmitted and/or absorbed. EMW absorption materials absorb the energy in electromagnetic waves as magnetic loss, and convert that energy, in the end, to heat. The effectiveness of the RF shielding can be specified in terms of an SAR reduction factor (SRF) and is defined as follows [5]:

$$SRF_{1g} (\%) = \frac{SAR_{1g} - SAR_{1g,s}}{SAR_{1g}} \times 100 \quad (2)$$

$$SRF_{10g} (\%) = \frac{SAR_{10g} - SAR_{10g,s}}{SAR_{10g}} \times 100$$

(3)

Where SRF_{1g} , is SRF for 1g peak SAR, SRF_{10g} , is SRF for 10g peak SAR, SAR_{1g} is 1g peak SAR (without RF shielding), $SAR_{1g,s}$ is 1g peak SAR (with RF shielding), SAR_{10g} is 10g peak SAR (without RF shielding), and $SAR_{10g,s}$ is 10g peak SAR (with RF shielding), respectively. It is observed that larger SRF value implies greater shielding effectiveness.

In this paper, the effect of various parameters like location, size, shape, and thickness of the RF shield on the SAR and the antenna performance are investigated by using the field simulation software, CST-MWS. Results have shown that SAR and SRF values change with the above mentioned parameters. There is no degradation of the radiation pattern but there is a slight variation in return loss with the use of RF shields. Simulation results will be useful for compliance testing of mobile phones.

2. MATERIALS

In our study, two tissue human head model is used. The radius of bone tissue is 10cm and that of brain tissue is 9cm. The mobile phone shown in figure1 was modeled as a perfect electric conductor (PEC) box, having external dimensions $2.5 \times 4.0 \times 12.0$ cm ($X \times Y \times Z$). A $\lambda/4$ cylindrical monopole antenna of 900MHz mounted on the top of the hand set box with 0.045cm radius is used as the radiating source. The monopole is also made by PEC. The 0.25cm gap is provided between top surface of the mobile phone box and cylindrical monopole. The antenna is fed at the junction between the monopole and the box. Monopole is excited by Gaussian pulse using discrete port. Literature survey revealed that mobile

phones as explained above are still in use in some part of the world, therefore it is used for our study.

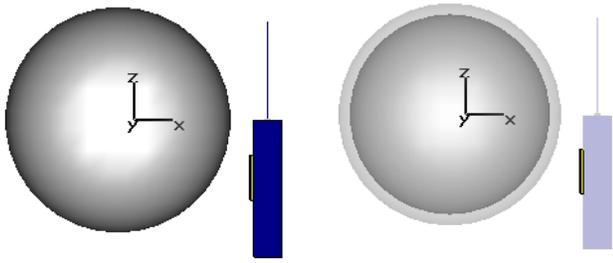

Figure1 (a) Model of human head and Mobile phone with RF shield attachment (b) Human head Model indicating two tissues.

An RF shield with a height of h cm, a width of 4 cm and a thickness of t cm is attached to the front surface of mobile phone box to evaluate SAR reduction. The mobile phones with different shapes of RF shield are shown in figure 2.

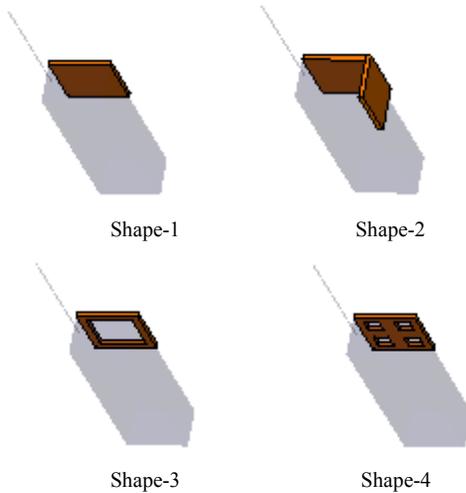

Figure 2. Different shapes of RF shield

2.1 Ferrimagnetic Material

The most important group of ferrimagnetic materials is the ferrites. In ferrites the conductivity is low which results in much smaller induced currents in the material when electromagnetic waves are applied. Also when an electromagnetic wave hits ferrite particles, the magnetic field part of the wave is cancelled [6].

Ferrites are ceramic materials with the general chemical formula $MOFe_2O_3$, Where MO is one or more divalent metal oxides blended with iron oxide. The iron oxide magnetite (Fe_3O_4), the nickel-zinc ferrite ($Ni_{1/2}Zn_{1/2}Fe_2O_4$), the Manganese-zinc ferrite and the nickel ferrite ($NiFe_2O_4$) are examples of this class of materials. Manganese-zinc ferrites have the highest permeabilities [6].

The dielectric parameter ($\epsilon_r, \sigma, \mu_r, \rho, \sigma_1 = \omega\epsilon_0\epsilon_r''$ =Electrical conductivity, $\sigma_2 = \omega\mu_0\mu_r''$ = Magnetic conductivity) values for modeling and simulation of RF shield,

mobile phone and spherical head model at 900 MHz are as listed in Table1.

Table 1. Summary of dielectric parameters

Material	ϵ_r	μ_r	Conductivity σ (s/m)	Density ρ (g/cm^3)
Air	1	1	0	1
Simulating Brain at 900 MHz	55	1	1.23	1.03
Simulating Bone at 900 MHz	8	1	0.105	1.85
RF shield at 900 MHz	$7.0-j0.6$	$2.8-j3.3$	$\sigma_1 = 0.030042$ $\sigma_2 = 23450.18$	5.27
PEC	PEC(Perfect electric conductor)			

3. METHOD

The commercial field simulation tool, CST Microwave Studio [7]... [10], which is based on the Finite Integration technique (FIT) was used to model RF shield, the mobile phone and the spherical head for evaluating the SAR reduction.

The basic parameters used for the simulation are as mentioned below:

The Perfect boundary approximation is used for spatial discretization. The mesh is produced by an automatic mesh generator, which ensures a good compromise between accuracy and simulation time.

Mesh properties used during simulations:

Mesh type: Hexahedral; Lines per wave length: 18; Lower mesh limit: 10; Mesh line ratio: 1.8; Minimum mesh step: 5; Maximum mesh step: 15; Mesh cells: 48544, an “add space” boundary condition representing the electromagnetic wave propagating towards the outer space is set.

Solver Type: Transient solver with following settings is employed.

Excited discrete port: 1; Excitation duration: $1.777274e^{-03}\mu s$; steady state accuracy limit: -30dB; Maximum number of time steps: 2764; Time step width: $1.285788e^{-05}\mu s$; Number of processors used: 01.

Two centimeter separation is assumed between the spherical head and a mobile phone. The antenna output power used for the simulation is 0.5 watt (rms). To See the effect of SAR reduction in the spherical head, the ferrite material that has electric and magnetic losses ($\epsilon_r = 7.0-j0.6, \mu_r = 2.8-j3.3$) is used as RF shield [5]. The antenna output power is defined as ; $P_{out} = P_{abs} + P_s + P_{rad}$ where P_{abs} is the power absorbed in the head model with a volume of V_h , P_s is the power

dissipated in the RF shield with a volume of v_s and p_{rad} is the power radiated to the far-field.

3.1 SAR Reduction Mechanism

Before deriving the SAR reducing effects using RF shield, the mechanism of SAR reduction [11] is discussed. For a monopole antenna mounted on a conducting box, the conducting box acts as a part of the antenna. The current flowing onto the conducting box spreads on all box surfaces. The local SAR on the head surface is roughly proportional to the squared surface-current-density on the box. Current density on the conducting box can be suppressed by attaching RF shield on to it which in turn reduces the corresponding surface SAR.

4. RESULTS AND ANALYSIS

The results discussed in this section are the effect of various parameters like location, size, shape, and thickness of the RF shield on the SAR, the return loss (S_{11}) and the far-field radiation pattern of the monopole antenna. Table 2 indicates the SAR(rms) value and S_{11} (return loss in db) when no RF shield is attached on to the front side of conducting box. Analysis of SAR and SRF given below is based on the results from Figure3-Figure8. Higher SRF indicates greater SAR reduction effect.

S_{11} (db)	Maximum SAR(w/kg)		Total SAR(w/kg) (rms)	Power (rms)	SRF (%)	
	1gm 10gm (rms)				1gm 10gm	
-7.10	0.50562	0.35031	0.0209922	0.1101	--	--

TABLE2. LOCAL SAR VALUES ON THE HEAD SURFACE
WITHOUT RF SHIELD

4.1 SAR Reduction Based on Location of RF Shield

To determine the location where the maximum surface current occurs, four locations of RF shielding attachment were assumed. The attaching location shown in Fig. 1 was named as location-1 in which the RF shield with 3 mm thickness, 4.0 cm width and 3.0 cm height was attached from $z = -0.1$ to -3.1 cm, then for location-2 from $z = -3.1$ cm to -6.1 cm, for location-3 $z = -6.1$ cm to -9.1 cm and for location-4 $z = -9.1$ cm to -12.1 cm. Figure 3 and Figure 4 indicate the relationship between the attaching location of RF shield and SAR and also SRF, the attaching location-2 has resulted in the maximum reduction for the SAR (i.e. SRF of 10.09 % for 1gm sample and 7.22% for 10gm sample) which corresponds to maximum surface-current-density on the box. This result imply that only suppressing the maximum current on the front side of conducting box contributes enough to the reduction of SAR.

4.2 SAR Reduction based on size of RF Shield

The size of RF shield with 3 mm thickness, 4.0 cm width is changed by changing height h (in z- direction) from 1 to 11 cm in steps of 1 cm. Figure 5 and Figure 6 shows the effect of size of RF shield on SAAR and SRF. SAR decreases with increase in size of ferrite sheet. Where as SRF increases with increase in size of ferrite sheet. As can be seen, RF shield with size 4×8 cm² is sufficient to get maximum SRF i.e. SRF of 16.47% for 1gm sample and 14.03% for 10gm sample.

4.3 SAR Reduction based on shape of RF Shield

In order to analyze the SAR and SRF data for different shapes, four shapes of RF shield with 3 mm thickness, 4.0 cm width and 4.0 cm height as shown in figure2 are attached on to the top front surface of the mobile phone. In Figure 7, for shape1 it is observed that SAR values are lower for 1gm sample and 10gm sample. There is no significant reduction in SAR with shape 2. SAR values are higher in shape3 compared to shape1. SAR values in case of shape4 are lowest among all shapes for 1gm sample and for 10gm sample. Thus SAR reducing effect with RF shield of shape4 is found to be more effective.

4.4 SAR Reduction based on thickness of RF Shield

RF shield of size 4.0×4.0 cm² is attached on to the front top surface of mobile phone. Shield thickness is varied from 0.5mm - 16mm. Figure 8 shows the effect of shield thickness variation on SAR. SAR obtained was highest for a thickness of 6 mm.

4.5 Return Loss (S_{11})

Figure9 shows the return loss (S_{11}) of the antenna as a function of the RF shield shape, location and size. It is observed that return loss do not change much as compared to without shield.

4.6 Radiation Pattern

Results have shown that attachment of RF shield on mobile phone not only reduces SAR in head model but also the radiated power. The point of concern here is whether suppression of surface current affects the radiation pattern. It is clear from figure 10 that no degradations in the radiation pattern with RF shield was observed as compared to without shield.

A personal computer with following configuration is used for computing simulations:

CPU : Pentium IV, 3GHz
RAM Memory : 504 MB

Operating System : Windows XP-Ver. 2002

5. CONCLUSIONS

In the present study various simulations are carried out in order to evaluate SAR reduction in the Spherical head model by attaching RF shield on to the front surface of mobile phone. The relationship between the attaching location, size, shape, thickness of RF shield and SAR reducing effect have been studied numerically by using field simulation software, CST MWS. Figure3 and Figure4 show that

attaching location-2 has resulted in the maximum reduction for the SAR. Figure5 and Figure6 reveal that SAR is decreased with increase in ferrite size. In Figure7, it is observed that SAR reducing effect with RF shield for shape4 is shown to be more effective. Figure8 shows the effect of shield thickness variation on SAR. SAR obtained was maximum for a thickness of 5 mm. Moreover, the RF shielding does not degrade the antenna performance. However there is slight variation in return losses when compared with RF shielding. So the RF shielding gives an option for compliance testing of mobile phones at the design stage.
