ABSTRACT

In this paper, Harris Corner Detector is proposed as a corner detection technique to extract palmprint features in the form of corners. Here, hamming distance similarity measurement using sliding window method is used as a feature matching method for the corners detected. The aim of using hamming distance method for corner matching is the non-dependency of the method with the number of corners detected. So, the comparison (matching) time will be constant with hamming distance feature matching method. We used the same feature matching technique in edge detection and got good results. In this paper, palmprint features are analyzed on different sigma, threshold and radius values. Experiments were developed on a database of 600 images from 100 individuals, with five image samples per individual for training and one image sample per individual for testing. The experimental results indicate that using Harris corner detector and Hamming distance using sliding window, recognition rate of 97.5% can be achieved.

Keywords

Palmprint, Feature extraction, Harris Corner Detector, Hamming distance.

1. INTRODUCTION

Palmprint-based personal authentication has found applications in pattern recognition, image processing and computer vision. Palmprint is considered one of the most reliable biometric because of its unique features [1-4]. The unique and stable features mean that there is minimal possibility of two different individual to have same palmprint features and to get matched as genuine. The palmprint are easy to capture and do not change over time and with age.

Palmprint consists of five types of features. They are geometry features, line features, point features, texture features, statistical features and points [5-7]. In this paper, Harris Corner Detector is proposed to detect the corners. The Harris corner detector is based on the local auto-correlation function of a signal; where the local auto-correlation function measures the local changes of the signal with patches shifted by a small amount in different directions [8-14]. Hamming distance similarity measurement using sliding window method is used as feature matching method.

The following section of the paper is organized as follows: Section 2 describes the basic of palmprint authentication system. In section 3 feature extraction by Harris Corner Detector technique is proposed. Section 4 presents feature matching by Hamming distance similarity measurement method using sliding window. Section 5 represents the training and testing stage. The

experimental results are presented in Section 6, while section 7 concludes the paper.

2. PALMPRINT AUTHENTICATION SYSTEM

In this paper, the palmprint authentication system is divided in following two subsystems:

- (a) Pre- Authentication System
- (b) Authentication System

In Pre-authentication system, a database of harris corner features and reference threshold value is prepared. These values will be used in Authentication system as shown in Figure 1.

In Authentication system, the authenticity of a person is identified with the help of Reference threshold value stored in database as shown in Figure 2.

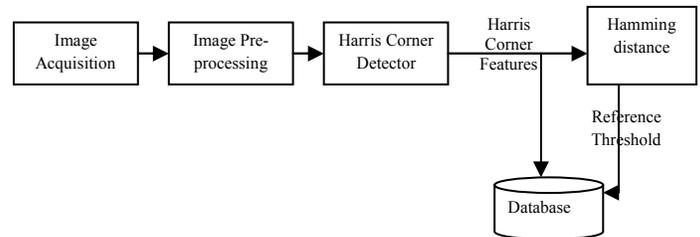

Figure 1: Palmprint Pre-Authentication system

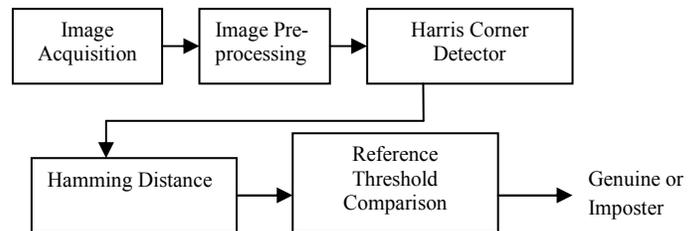

Figure 2: Palmprint Authentication System

3. FEATURE EXTRACTION USING HARRIS CORNER DETECTOR

The ‘corner’ is defined as a location in the image where the local autocorrelation function has a distinct peak. Corner point detection has found its application in various computer vision tasks. Here, Harris corner detector is proposed to extract corner information for palmprint authentication.

Harris Corner Detector is one of the promising tool to analyze the corner points. Harris Corner Detector is based on the autocorrelation of image intensity values or image gradient values. The gradient covariance matrix is given by:

$$G_{x,y} = \begin{bmatrix} \left(\frac{\partial I}{\partial x}\right)^2 & \frac{\partial I}{\partial x} \frac{\partial I}{\partial y} \\ \frac{\partial I}{\partial y} \frac{\partial I}{\partial x} & \left(\frac{\partial I}{\partial y}\right)^2 \end{bmatrix} = \begin{bmatrix} I_x^2 & I_x I_y \\ I_x I_y & I_y^2 \end{bmatrix} \quad (1)$$

where I_x and I_y denote the image gradients in the x and y directions. Harris Corner Detector considers the minimum and maximum eigenvalues, α and β , of the image gradient covariance matrix $G_{x,y}$ in developing corner detector. A ‘corner’ is said to occur when the two eigenvalues are large and similar in magnitude. Harris [11-12] devises a measure using the determinant and trace of the gradient covariance matrix as:

$$R = \alpha\beta - k(\alpha + \beta)^2 = \det G - k(\text{Trace}(G))^2 \quad (\text{with } k \in [0.04, 0.06]) \quad (2)$$

On the basis of R the pixels are classified as follows:

$$R > 0 : \text{Corner pixel}, \quad R \simeq 0 : \text{pixel in flat region}, \quad R < 0 : \text{edge pixel}. \quad (3)$$

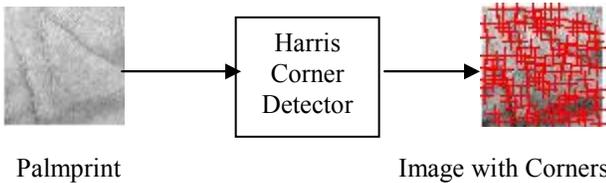

Figure 3: Corner detection by Harris corner detector on palmprint image, ‘+’ defines the corners detected.

The feature vector consists of palmprint features or corners detected.

$$FV = \text{Palmprint features (PF)} \quad (4)$$

The corner features extracted by Harris corner detector method are analyzed on different values of sigma, threshold and radius. The number of corners detected varies with varying values of sigma, threshold and radius as shown in Fig. 4 and binarized corner information is shown in Fig. 5(in the end of paper).

4. HAMMING DISTANCE SIMILARITY MEASUREMENT USING SLIDING WINDOW METHOD

In this paper, a new corner matching technique using hamming distance similarity measurement is proposed. We have matched palmprint line feature vectors by Hamming distance similarity measurement method and got good results in edge detection method. Here, hamming distance method is used on palmprint corner features that work on binary feature vectors. The corner information (Palmprint features) extracted is binarized by the following equation (5):

$$PF(i, j) = \begin{cases} 1, & PF(i, j) > 0 \\ 0, & PF(i, j) \leq 0 \end{cases} \quad (5)$$

where, $PF(i, j)$ = Palmprint features, i and j are the rows and columns of the Palmprint features.

The hamming distance similarity measurement using XOR operation between two binary feature vectors can be defined as:

$$HD = \sum_i \sum_j (FV(i, j) \oplus FV_{DB}(i, j)) \quad (6)$$

Sliding window technique is used to avoid false rejection because of displaced ROI. Suppose, if the ROI is displaced by two rows, there are chances of the ROI not getting matched with the same ROI present in the database because of displacement in the rows. Here, to overcome the displacement problem, sliding window method with reduced ROI by some window size WS is used. For window size WS , ROI area of $(64-WS) \times (64-WS)$ pixels out of 64×64 pixels slides over the rows and columns using Hamming distance matching and minimum of the value is considered. Fig. 6 shows the sliding window method used to find the hamming distance.

The hamming distance value with window size WS is defined as:

$$HD_{WS} = \sum_i \sum_j (FV(i, j) \oplus FV_{DB}(i, j)) \quad (7)$$

where HD_{WS} denotes the hamming distance with window size WS , i and j is the row and column of the Palmprint feature vector, \oplus is the exclusive OR operation, WS denotes the window size, FV_{DB} denotes the feature vector in database. For window size WS (4), there will be $WS \times WS$ ($4 \times 4 = 16$) hamming distance values. The minimum value out of 16 values of hamming distances is chosen as hamming distance.

$$HD = \min(HD_1, HD_2, HD_3, \dots, HD_{16}) \quad (8)$$

where, HD denotes the hamming distance value.

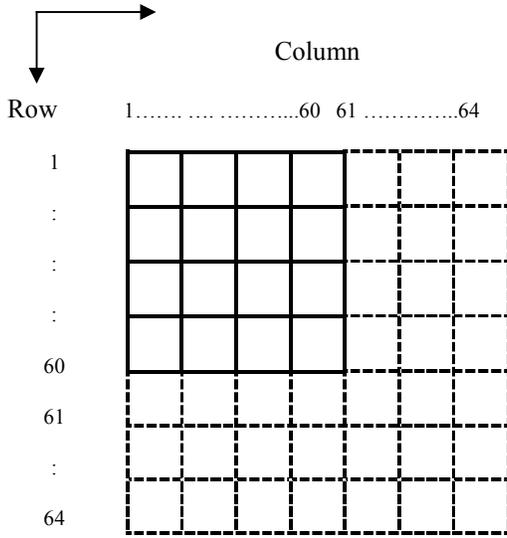

Figure 6: Sliding Window Approach with window size 4 and palmprint size 64x64

Hamming Distance value “1” signifies both feature vectors are exactly same and a value near to “1” is identified as reference threshold. If matching score (or Hamming distance) of two feature vectors is less than reference threshold value, feature vectors are considered to be from same hands otherwise different hands. The accuracy of the biometric authentication can be defined by following equation (9):

$$Accuracy(\%) = (100 - (FAR(\%) + FRR(\%)) / 2) \quad (9)$$

Where, FAR is False Acceptance Rate, FRR is False Rejection Rate. If either FAR or FRR is decreased, overall system accuracy is increased.

5. TRAINING AND TESTING STAGE

The hand image samples are divided into two groups G1 (Training group) and G2 (Testing group).

G₁ group

$$P_1 = [I_1, I_2, \dots, I_{(M-1)}], P_2 = [I_1, I_2, \dots, I_{(M-1)}], \dots, P_N = [I_1, I_2, \dots, I_{(M-1)}] \quad (10)$$

G₂ group

$$P_1 = [I_M], P_2 = [I_M], \dots, P_N = [I_M] \quad (11)$$

Where P_i denotes ith person in group G₁, G₂, I_j denotes the jth palm image in group G₁, G₂.

As shown in table 1, for group G1, each hand feature vector in P₁ is matched with all other (M-1) hands feature vector by Hamming distance similarity measurement method. The matching values are stored in threshold array.

$$TA_1 = \begin{bmatrix} HD_{12}, HD_{13}, \dots, HD_{1(M-1)}, HD_{21}, HD_{22}, \dots \\ HD_{2(M-1)}, \dots, HD_{(M-1)1}, HD_{(M-1)2}, \dots \\ \dots \\ HD_{(M-1)(M-2)} \end{bmatrix} \quad (12)$$

Table.1: Matching in Group G₁ among Person P₁.

i \ j	1	2	3	...	M-1
1	X	HD ₁₂	HD ₁₃	HD _{1(M-1)}
2	HD ₂₁	X	HD ₂₃	HD _{2(M-1)}
⋮	⋮	⋮	⋮	⋮	⋮
⋮	⋮	⋮	⋮	⋮	⋮
M-1	HD _{(M-1)1}	HD _{(M-1)2}	HD _{(M-1)3}	X

Similarly, all N hand image samples matching results are stored in Threshold array (TA).

$$T_A = TA_1 + TA_2 + \dots + TA_N \quad (13)$$

The minimum and maximum of matching values are found out from the threshold array (TA₁, TA₂,.....TA_N) for each individual as shown in equation (14).

$$\left. \begin{aligned} T_{AiMIN} &= \min(T_{Ai}) \\ T_{AiMAX} &= \max(T_{Ai}) \end{aligned} \right\}_{i=1, \dots, N} \quad (14)$$

The accuracy of the system is identified by matching group G₂ samples with group G₁ samples using threshold values stored in threshold array. Finally, a threshold value is chosen where FAR and FRR is minimum, this value is called Reference threshold.

In palmprint authentication system, two palmprints are matched and the comparison of matching score values with reference threshold value defines the authenticity of the person. The authentication system is shown in Fig. 7.

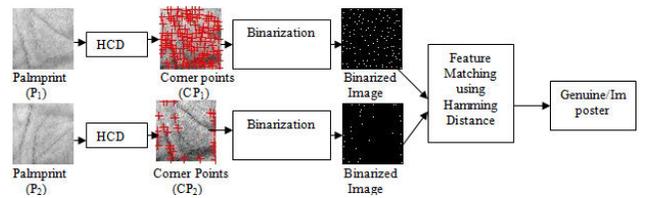

Figure 7: Authentication System

6. EXPERIMENTAL SETUP

A database of 600 palmprint images from 100 palms with 6 samples for each palm is taken from PolyU palmprint database [21]. The palmprint database is divided into two groups, first group (G_1) consists of 100 persons with each person having 5 palm sample images to train the system, and second group (G_2) contains 100 persons with each person having one palm image different from the first group images. Second group is used as testing sample.

G_1 group

$$P_1 = [I_1, I_2, I_3, I_4, I_5],$$

$$P_2 = [I_1, I_2, I_3, I_4, I_5], \dots P_{100} = [I_1, I_2, I_3, I_4, I_5]$$

In G_1 group each hand P_i contains 5 sample image I_{1-5} .

G_2 group

$$P_1 = [I_6], P_2 = [I_6], \dots P_{100} = [I_6]$$

In G_2 group each hand P_i contains only sample image I_6 .

Image is pre-processed to get the region of interest. Pre-processing includes image enhancement, image binarization, boundary extraction, cropping of palmprint/ROI. Feature extraction is done by Harris Corner Detector to get the corners from the palmprint image. The proposed feature extraction method is applied on the palmprint image to get Palmprint Corner features. Feature vector of all hand images samples is calculated and stored in database. Hamming distance similarity measurement method is used as a feature matching method.

6.1 Reference Threshold Calculation

In group G_1 , each hand feature vector in P_1 is matched with all other 4 hands feature vector by Hamming distance similarity measurement method as shown in Fig. 8.

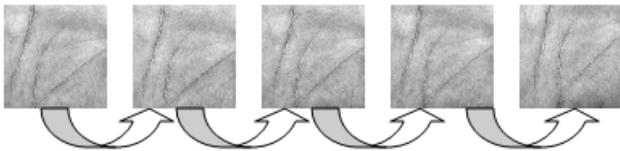

Figure 8: Matching of palmprints with each other

Similarly, all 100 hand image samples 2000 matching values are stored in Threshold array (TA).

$$T_A = TA_1 + TA_2 + \dots + TA_{100}$$

$$T_{AiMIN} = \min(T_{Ai})$$

$$T_{AiMAX} = \max(T_{Ai}) \quad \left. \vphantom{T_{AiMIN}} \right\} \quad i=1, \dots, 100$$

The maximum and minimum values are found out from threshold array. The value of reference threshold is chosen

where FAR and FRR values are minimum. The threshold, sigma, radius, number of corners, comparison time and accuracy are tabulated in table 2. From the table 2 (shown in the end of paper) it is clear that the comparison time is non-dependent on the number of corners detected. The maximum accuracy value is identified at threshold value 900, sigma value 3 and radius value 1. The respective reference threshold value, FAR and FRR are values are tabulated at maximum value of accuracy corresponding to threshold value 900, sigma value 3 and radius value 1 in table 3.

Table 3: Comparison of FAR and FRR with Accuracy at Window Size 2.

Reference Threshold	FAR	FRR	Accuracy
9.81E-01	4.98E-02	7.45E-03	9.71E+01
9.83E-01	4.29E-02	6.90E-03	9.75E+01
9.85E-01	3.93E-02	6.02E-03	9.77E+01
9.87E-01	3.74E-02	4.66E-03	9.79E+01
9.89E-01	3.15E-02	4.08E-03	9.82E+01
9.91E-01	2.82E-02	3.04E-03	9.84E+01
9.93E-01	2.82E-02	3.04E-03	9.84E+01
9.95E-01	2.45E-02	2.44E-03	9.87E+01
9.97E-01	2.08E-02	2.23E-03	9.88E+01

Plot of FAR and FRR values mentioned in table 3 is shown in Fig. 9.

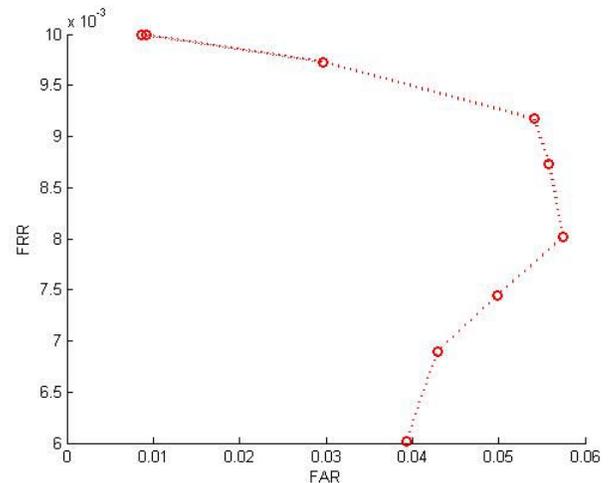

Figure 9: FAR Vs FRR.

The plot between accuracy and threshold is shown in Fig. 10.

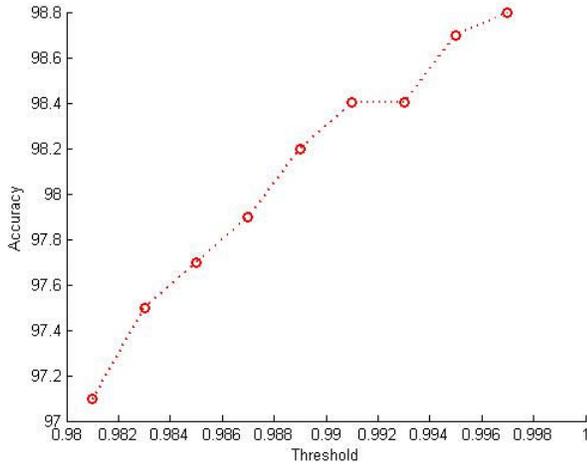

Figure 10: Threshold Vs Accuracy.

6.2 Comparison of Hamming distance similarity measurement and Match by Correlation

As discussed earlier that hamming distance similarity measurement method is non-dependent on the number of corners detected, so the comparison time is constant. In case of Match by correlation method, comparison time depends on the number of corners detected. The number of corners detected is directly proportional to the time taken.

Table 4: Comparison of Matching Time with Hamming Distance and Match By Correlation Method

Threshold	Sigma	Radius	Number of corners	Comparison Time	
				Hamming distance	Match by Correlation
100	1	1	107	3.05E-03	5.69E+00
100	1	2	60	3.13E-03	8.65E+00
100	1	3	23	3.24E-03	8.70E+00
100	2	1	35	3.28E-03	8.91E+00
100	2	2	27	3.28E-03	1.00E+01
100	2	3	21	3.28E-03	1.16E+01
100	3	1	21	3.45E-03	1.24E+01
100	3	2	16	3.23E-03	1.41E+01
100	3	3	15	3.38E-03	1.33E+01

Table 4 shows the comparison of matching time of hamming distance method and match by correlation method on harris corner operator for threshold value of 100 and various values of

sigma and radius is tabulated in table 4. It can be concluded from table IV that the harris corner method performs better with hamming distance method as hamming distance matching method involves EX-OR operation which is very fast operation. The values of parameters used in experimental results are shown in table 5.

Table 5: Summary of the Values Used for Experimental Results

Parameters	Values
Feature Extraction method	Harris Corner Detector
Feature matching method	Hamming distance
Min Threshold	9.75E-01
Max Threshold	9.89E-01
Reference Threshold	9.83E-01
Sliding window size	2
Sigma	3
Threshold	900
Radius	1
Comparison Time	3.12E-03
DB Preparation Time	2.87E-02
FAR	4.29E-02
FRR	6.90E-03
Accuracy	97.5

The combination of harris corner operator and hamming distance method makes the real time authentication system fast and accurate with less comparison time value and high recognition rate.

6.3 Methods Comparison

The comparison of different palmprint authentication methods is tabulated in table 6.

Table 6: Methods Comparison with Harris Corner Detector

	Wang et al. [15]	Li et al. [16]	Han et al. [17]	Proposed Approach
Size of database	500	1380	50	100
Feature extraction method	Fourier Transform	Directional line detector	Sobel & Morphological	Harris Corner Detector

Feature Matching method	Distance formula	Palmprint Classification	Multi-template-matching	Hamming distance
Accuracy	95.48	96.03	91	97.5%

7. CONCLUSION

In this paper, we have presented a promising approach of Harris corner detector for palmprint feature extraction. The corner information extracted using Harris corner detector is compared with other feature vector in the database using Hamming distance similarity measurement method using sliding window method. It is observed in the results that the sliding window method takes less time in matching the feature vectors as compared to match by correlation method. This shows that sliding window method does not depend on the number of corners detected. It can be concluded that feature matching by sliding window method has come out to be best method with high accuracy and less comparison (matching) time. Experimental results clearly show that Harris corner detector methodology has the ability to discriminate similar palmprints with recognition rate of 97.5%. The high accuracy and less comparison time make this system rapid, genuine and reliable authentication system.
